

The Jimple methods used to create statements and expressions in lab4

API Method Signature	Description
<code>Jimple.newGotoStmt (Unit)</code>	create new goto statement branching to the statement given as argument. Return type of <code>newGotoStmt()</code> : <code>GotoStmt</code> which is a subinterface of <code>Unit</code> .
<code>Jimple.newNopStmt ()</code>	create a new nop statement. Return type of <code>newNopStmt()</code> : <code>NopStmt</code> which is a subinterface of <code>Unit</code> .
All the following <code>Jimple.new*Expr ()</code>	The (two) argument(s) needs to be a constant or a local.
<code>Jimple.newEqExpr (Value, Value)</code>	create a new “==” expression. Return type of <code>newEqExpr()</code> : <code>EqExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newAddExpr (Value, Value)</code>	create a new “+” expression. Return type of <code>newAddExpr()</code> : <code>AddExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newSubExpr (Value, Value)</code>	create a new “-” expression. Return type of <code>newSubExpr()</code> : <code>SubExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newMulExpr (Value, Value)</code>	create a new “*” expression. Return type of <code>newMulExpr()</code> : <code>MulExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newDivExpr (Value, Value)</code>	create a new “/” expression. Return type of <code>newDivExpr()</code> : <code>DivExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newRemExpr (Value, Value)</code>	create a new “%” expression. Return type of <code>newRemExpr()</code> : <code>RemExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newNegExpr (Value)</code>	create a new unary minus expression. Return type of <code>newNegExpr()</code> : <code>NegExpr</code> which is a subinterface of <code>Value</code> .
<code>Jimple.newArrayRef (Value, Value)</code>	create a new array index expression of the form <code>a[i]</code> . The two arguments need to be locals. Return type of <code>newArrayRef()</code> : <code>ArrayRef</code> which is a subinterface of <code>Value</code> .
<code>IntConstant.v (int)</code>	create a new integer literal. <code>IntConstant</code> is a class implementing the <code>Value</code> interface.
<code>StringConstant.v (String)</code>	create a new string literal. <code>StringConstant</code> is a class implementing the <code>Value</code> interface.
